

## ELECTRICAL CAPPED CONTACT STUD AND METHOD OF FASTENING AN ELECTRICAL CONTACT

The invention relates to an electrical contact stud, in particular for fastening an  
5 electrical earth contact, with a shank, having an external thread, and an adjoining  
contact flange with a contact face facing the shank; a cap nut for electrical contact  
studs; an electrical contact system, in particular for fastening an electrical earth  
contact; and a method for fastening an electrical contact to a workpiece to be painted.

10 A typical case of application for this is in automotive construction, where  
threaded studs, which can be welded on, soldered on or riveted, are used as electrical  
contact studs for fastening an electrical contact.

From EP 0 640 404 A1 a method is known, by which an electrical contact  
15 between a contact shoe and a sheet of metal to be painted is produced with the aid of a  
threaded stud and a cap nut. The cap nut is herein used in two ways. On the one hand  
the cap nut protects the threaded stud from being coated with paint during the painting  
process and on the other hand with the aid of the cap nut a contact shoe is fastened to  
the threaded stud. The advantage of this method, which uses metal cap nuts, is that by  
20 using the cap nut both as covering cap and as fastening element unnecessary waste in  
the form of covering caps covered with paint is avoided, as described in the prior art,  
for example of EP 0 243 078 B1.

A disadvantage of the known method is that the cap nut is a relatively expensive  
25 component if it is made of metal and that it has to be tightened with a large torque  
against the contact shoe, so that it does not come loose. However, large torques or  
large forces present a problem with mechanically sensitive workpieces, such as, for  
example thin sheets of metal, as they can cause deformations or damage to the  
workpiece when the nut is tightened.

30

It is therefore the object of the present invention to create economically an  
electrical contact stud, a cap nut, an electrical contact system and a method for

## ELECTRICAL CAPPED CONTACT STUD AND METHOD OF FASTENING AN ELECTRICAL CONTACT

The invention relates to an electrical contact stud, in particular for fastening an  
5 electrical earth contact, with a shank, having an external thread, and an adjoining  
contact flange with a contact face facing the shank; a cap nut for electrical contact  
studs; an electrical contact system, in particular for fastening an electrical earth  
contact; and a method for fastening an electrical contact to a workpiece to be painted.

10 A typical case of application for this is in automotive construction, where  
threaded studs, which can be welded on, soldered on or riveted, are used as electrical  
contact studs for fastening an electrical contact.

From EP 0 640 404 A1 a method is known, by which an electrical contact  
15 between a contact shoe and a sheet of metal to be painted is produced with the aid of a  
threaded stud and a cap nut. The cap nut is herein used in two ways. On the one hand  
the cap nut protects the threaded stud from being coated with paint during the painting  
process and on the other hand with the aid of the cap nut a contact shoe is fastened to  
20 the threaded stud. The advantage of this method, which uses metal cap nuts, is that by  
using the cap nut both as covering cap and as fastening element unnecessary waste in  
the form of covering caps covered with paint is avoided, as described in the prior art,  
for example of EP 0 243 078 B1.

A disadvantage of the known method is that the cap nut is a relatively expensive  
25 component if it is made of metal and that it has to be tightened with a large torque  
against the contact shoe, so that it does not come loose. However, large torques or  
large forces present a problem with mechanically sensitive workpieces, such as, for  
example thin sheets of metal, as they can cause deformations or damage to the  
workpiece when the nut is tightened.

30

It is therefore the object of the present invention to create economically an  
electrical contact stud, a cap nut, an electrical contact system and a method for

fastening an electrical contact, whereby electrical contacts can be fastened to particularly sensitive workpieces, for example thin sheets of metal.

This object is achieved according to the invention by an electrical contact stud  
5 with the features according to claim 1, by a cap nut with the features according to  
claim 8, by an electrical contact system with the features according to claim 17 and by  
a method with the features of claim 20. Particular features and advantageous  
configurations, which can occur individually or in combination, are the subject of the  
respective dependent claims.

10

A substantial idea of the invention, which has an effect in all the components of  
the system, is the use of a cap nut made of a plastics material for fastening an  
electrical contact, which has so far not been considered owing to the electrically  
insulating property of most plastics materials. Tests have, though, surprisingly shown  
15 that the transition resistance of the system according to the invention is only  
minimally greater than that of completely metal systems, and in fact irrespective of  
whether an electrically conductive or an electrically insulating plastics material is  
chosen.

20

The electrical contact stud according to the invention, in particular for fastening  
an electrical earth contact with a shank which has an external thread and an adjoining  
contact flange with a contact face facing the shank is characterised in that the shank  
with the external thread is designed for screwing down a cap nut made of plastics  
material with a torque of at least 4 Nm, in particular at least 6 Nm, preferably  
25 approximately 8 Nm.

30

With the aid of the electrical contact stud a mechanical and electrical contact is  
produced on a workpiece, in particular on a sheet of metal. The contact stud can have  
a diameter between 4 and 10 mm, in particular between 6 and 8 mm. With the aid of  
the external thread on the shank a cap nut can be screwed down, with which the  
electrical contact, in particular an electrical contact shoe, is fastened. The electrical  
contact is produced between the contact shoe and the contact face facing the shank.

The transition resistance mainly depends of these two surfaces, so the electrical properties of the cap nut do not matter.

- According to the invention for producing an electrical contact only
- 5 comparatively low torques are required, so electrical contacts can be fastened even to very thin sheets of metal, in particular also on sheets of metal with thicknesses < 0.6 mm, preferably < 0.5 mm. With the aid of the contact flange the electrical contact stud is fastened over a wide area on a workpiece, in particular a sheet of metal. The larger torques customary with electrical contacts in the prior art serve mainly for securing
- 10 against loosening of the nut, which can be achieved with plastics material nuts by constructive measures for achieving self-securing without torques of this kind. Basically, however, comparably large torques as with metal nuts can also be applied with cap nuts according to the invention, if this is required or desired.
- 15 The contact flange thus has on the one hand the purpose of achieving adequate mechanical strength of the contact stud on the workpiece and on the other hand the purpose of making available a sufficiently large contact area for an electrical contact.

- In one configuration of the invention the ratio of the inclination of the external
- 20 thread to the diameter of the shank is at least 1:5, in particular at least 1:4, preferably approximately 1:3. In comparison to electrical contact studs for metal cap nuts a ratio of this kind of the inclination of the external thread to the diameter of the shank is very much larger. Owing to a ratio of this kind the thread of a cap nut made of plastics material is prevented from being pulled out.

- 25 In an advantageous configuration of the invention the ratio of the thickness of the contact flange to the diameter of the shank is at least 1:2, in particular 1:1.5, preferably approximately 1:1. By means of contact flanges of this kind of thickness reliable gripping of the electrical contact stud by holding tongs is made possible.
- 30 Lateral tilting is prevented. The good electrical contact between electrical contact stud and the holding tongs necessary in a stud welding method with arc is guaranteed.

In a particular configuration of the electrical contact stud according to the invention the contact flange has on its side opposite the contact face a welding portion, preferably with a blunt conical projection. With the aid of the welding portion a welding connection is produced between the contact flange and a workpiece, in particular a sheet of metal. With the aid of the conical projection igniting a defined arc is made possible during the stud welding process. These parts are no different from those in customary earth studs for welding, as known in the prior art.

In an advantageous configuration of the invention the contact flange has a customary tool engagement region. With the aid of the tool engagement region the electrical contact stud can be gripped by a tool and the cap nut screwed down, without the workpiece, to which the electrical contact stud is fastened, being under mechanical strain. In addition the tool engagement region can be used to tighten the cap nut if the electrical contact stud has not yet been fastened to the workpiece and the contact face of the electrical contact stud is to be protected by a cap nut.

In a special configuration of the electrical contact stud according to the invention the shank has a bezel on its open end. With the aid of the bezel on the one hand screwing down the cap nut is made easier and on the other hand the danger of damage by sharp edges is avoided.

In a particularly advantageous configuration of the invention the electrical contact stud is provided with a particularly corrosion-proof and electrically contact-conveying coating, in particular a tin-zinc alloy. By means of a coating of this kind, which can be applied, for example, by galvanising, ageing processes of the contact faces, which could lead to an increase in the contact resistance and therefore to a reduced conductivity, are suppressed.

A cap nut according to the invention made of plastics material, in particular for fastening an electrical earth contact, with a cap and a front face, wherein the front face has a thread orifice containing an internal thread, is characterised in that the internal thread is designed in such a way and the material of the cap nut is of such a kind that

the cap nut can be tightened on a corresponding external thread against a contact face with a torque of at least 4 Nm, in particular 6 Nm, preferably 8 Nm.

The design and the material of the cap nut are chosen in such a way that torques  
 5 of this kind can be absorbed. These torques are definitely in the range of torques normally used with metal cap nuts. However, plastics material nuts can be designed in such a way that self-securing against accidental loosening begins even with lower torques. As the electrical contact does not necessarily require large torques, the effect of torques or of forces on the workpiece can be reduced without the danger of  
 10 loosening the nut. The torques used are nevertheless adequate to produce a good electrical contact between an electrical contact shoe and the contact face with the cap nut.

As the cap nut consists of plastics material, for its part it does not contribute to  
 15 the electrical contact. It simply presses the contact shoe against the contact face. The pressure forces generated by the application of a torque on the cap nut are possibly smaller in comparison with metal cap nuts, but contrary to expectation are adequate for a good electrical contact. Metal cap nuts do not require a higher torque owing to the electrical resistance, but in order to effect self-catching of the cap nut. The high  
 20 torques are not required for producing a smooth electrical contact and place unnecessary strain on the connection between contact stud and workpiece.

In an advantageous configuration of the cap nut according to the invention made  
 25 of plastics material the ratio of the inclination of the internal thread to the diameter of the thread orifice is at least 1:5, in particular at least 1:4, preferably approximately 1:3. In order to guarantee adequate strength of the cap nut for the required torques and to prevent the internal thread being pulled out, ratios of this kind of the inclination of the internal thread to the diameter of the thread orifice are advantageous. By means of a ratio of this kind it is prevented that the cap nut is pulled out owing to excess stress.  
 30 In general a larger ratio is advantageous for firmer plastics materials; a smaller ratio is necessary for softer plastics materials. With plastics material nuts, owing to the elasticity of the material, a ratio of this size is adequate to achieve self-catching.

If it is desired that the cap nut contributes to the electrical contact, according to the invention the cap nut is made of conductive plastics material. The plastics material of the cap nut can be provided with enclosed metal filaments which can be incorporated into the moulding compound in a known manner during injection moulding. The distribution of the metal filaments in the plastics material can be random. This configuration of the cap nut will provide, in comparison with a cap nut made of metal, a sufficient conductive cross-section for the subsequent use as earth terminal. A smaller dimension with which the cap nut can be screwed onto the stud produces a completely connected contact face between the internal screw thread of the cap nut and the external thread of the stud which contributes considerably to increasing the conductive cross-section. In addition to direct introduction of the electric current into the flange of the stud from the cable lug, the current can also flow into the cap nut and via the internal thread and the external thread into the threaded shank of the stud.

15

In a preferred configuration of the cap nut according to the invention the cap nut is made of a plastics material which can withstand particular mechanical strain, in particular of polyamide reinforced by glass fibre. The proportion of glass fibre in the plastics material is at least 10%, in particular at least 20%, preferably approximately 20% of the weight. Owing to the glass fibres a particular strength of the plastics material is achieved, which allows absorption of the necessary torques by the cap nut.

25

In an advantageous configuration of the cap nut according to the invention the cap has a centring point, as is known per se as an assembly aid for components of this kind made of plastics material. With the aid of the centring point the cap nut can be centred during screwing down and the electrical contact stud, onto which the cap nut is screwed, can be centred during gripping for the placing process.

30

In a further advantageous configuration of the invention the front face of the cap nut has a sealing flange. With the aid of the sealing flange a particularly good seal against penetration of paint is achieved, so the electrical contact faces are protected from paint which could make the electrical contact heavier.

According to the invention it is advantageous to design the front end with an obtuse-angled, conical recess, which forms outwardly a kind of sealing lip. With the aid of the sealing lip a particularly good seal against paint is produced. Alternatively 5 the sealing lip is formed by at least one bridge, which runs along the periphery of the sealing flange on the front end of the cap nut.

In a special configuration of the cap nut according to the invention the internal 10 thread is formed with smaller dimensions. By means of the thus formed internal thread particularly good self-catching of the cap nut is generated, which makes independent loosening of the cap nut from an electrical contact stud more difficult or avoids it.

15 In a further special configuration of the cap nut according to the invention the cap has a tool engagement region. With the aid of the tool engagement region the cap nut is gripped by a tool and can be tightened. The tool engagement region can be provided in cross-section by a hexagon.

The electrical contact system according to the invention, in particular for 20 fastening an electrical earth contact comprising an electrical contact stud, in particular an electrical contact stud according to the invention, and a cap nut made of plastics material, in particular a cap nut according to the invention, is characterised in that the electrical contact stud has a shank with an external thread and an adjoining contact flange and the cap nut has a front end with thread orifice containing an internal thread, 25 wherein the cap nut can be tightened with a torque of at least 4 Nm, in particular at least 6 Nm, preferably 8 Nm, against the contact flange.

The electrical contact system according to the invention allows fastening of an 30 electrical contact to a workpiece with low transition resistance in spite possibly of comparatively low torques. The cap nut made of plastics material makes large torques, which are necessary, for example, with metal cap nuts, unnecessary. It is simultaneously capable of effecting adequately large pressing forces, which are

necessary for constructing an electrical contact. With the aid of the electrical contact system the effects of forces or torques during fastening of the electrical contact onto the workpiece are reduced. This enables electrical contacts to be fastened even with thin sheets of metal with sheet metal thicknesses of less than 0.6 mm or even less than 5 0.5 mm. A plastics material nut with complex structure can therein be economically produced and has a lower weight than a metal nut.

In an advantageous configuration of the contact system according to the invention to produce self-catching the inclination of the internal thread is different 10 from the inclination of the external thread. Owing to the different inclinations the internal thread of the cap nut is elastically deformed, whereby friction forces between cap nut and electrical contact stud are reinforced. The incommensurability of the two thread inclinations effects further protection with respect to undesired loosening of the nut from the electrical contact stud.

15

In a further advantageous configuration of the electrical contact system according to the invention for producing self-catching the diameter of the thread on the shank is at least 2%, in particular at least 6%, preferably 8% larger than the diameter of the thread orifice. Owing to the difference in diameter the cap nut is 20 braced on the electrical contact stud. In this way additional friction forces are generated for self-catching and a low transition resistance is achieved when the cap nut is made of conductive plastics material.

The method according to the invention for fastening an electrical contact to a 25 workpiece to be painted using an electrical contact stud, in particular an electrical contact stud according to the invention, and a cap nut, in particular a cap nut according to the invention, comprises the following method steps: the cap nut is tightened on the contact stud with a torque of at least 1 Nm, maximum 4 Nm, preferably approximately 3 Nm; the contact stud is fastened to the workpiece; paint is applied to the workpiece; the cap nut is loosened from the contact stud; an electrical 30 contact shoe is placed in between; the electrical contact shoe is pressed by tightening.

the cap nut with a torque of more than 4 Nm, preferably more than 6 Nm, in particular approximately 8 Nm.

5 The cap nut has on the one hand the function of protecting the contact stud from paint and on the other hand with it the mechanical and therefore the electrical contact is produced. The torques used are smaller by comparison with known methods, whereby application of the method can be carried out even with very thin sheets of metal.

10 The sequence of the steps of the method can be partially interchanged. In particular the electrical contact can first be fastened, whereupon the cap nut is tightened. In any case it is important that the cap nut is tightened to the contact stud before the paint is applied, so that the contact stud is protected from paint. With the aid of the method according to the invention electrical contacts are generated which 15 are comparable in quality to the contacts produced with metal cap nuts. The respective electrical contact resistances coincide to within a few percent.

The contact stud can be fastened to the workpiece by welding, soldering or riveting.

20 The cap nut made of plastics material can be tinted in a simple manner by a corresponding additive to the plastics material. The colour can be enlisted for identifying the cap nut, in particular its task or its size.

25 In a particular configuration of the invention the cap nut is elastically or plastically deformed on first tightening. Owing to the elastic or plastic deformation a particularly good seal is achieved, whereby the electrical contact stud is particularly effectively protected from paint. By an elastic or plastic deformation, in particular during the second tightening particularly good self-catching of the cap nut is further effected after final assembly.

Further advantageous configurations and characteristic features, which can occur individually or in combination, are described using the following drawings. The drawings are not, however, intended to restrict the invention, but are intended to depict the invention only as an example.

Fig. 8 shows various method sequences of the method according to the invention for fastening an electrical contact to a workpiece to be painted using an electrical contact stud and a cap nut.

20 Fig. 1 shows an electrical contact stud 1 according to the invention in side view with a shank 2, connected to a contact flange 3, wherein the contact flange 3 can be fastened to a workpiece 11 (not depicted) with the aid of a welding portion 23 and a conical projection 9. The contact flange 3 produces on one of its sides a mechanical contact with the workpiece and on the other side an electrical contact with a contact shoe 21 (not depicted) with the aid of its contact face 4. The shank 2 has an external thread 5, with which a cap nut 12 (not depicted) can be fastened. Contact studs 1 of this kind typically have a T6 external thread and are tightened with a torque of 6 to 8

25 30 Nm.

The ratio of the thickness DF of the contact flange to the diameter DS of the shank is approximately 1:1. This enables the electrical contact stud 1 to be gripped by a stud setting machine in a simple manner and an adequately good electrical contact to be achieved between stud setting machine and electrical contact stud during stud welding. The shank 2 has a bezel 10 on its open end. The ratio of the inclination SA of the external thread to the diameter DS of the shank 2 is 1:3. This large ratio is particularly suitable for screwing down cap nuts 12 made of plastics material. With the aid of the conical projection 9 an arc is generated during stud welding, starting from the point of the conical projection 9. The portion 23 is pressed into the liquid 10 molten mass after the workpiece has been heated.

Fig. 2 shows the electrical contact stud 1 according to the invention according to Fig. 1 in cross-section. The shank 2 and the diameter DS of the shank 2 can be seen, as well as the tool engagement region 20 with which the electrical contact stud 1 can 15 be gripped by a tool (not depicted).

Fig. 3 shows a cap nut 12 according to the invention with a thread orifice 13 containing an internal thread 6, wherein the ratio of the inclination SI of the internal thread 6 to the diameter DG of the thread orifice 13 is approximately 1:3. Cap nuts 12 of this kind typically have an M6 internal thread 6 and are tightened with 20 approximately 9.6 Nm. The cap nut 12 has a tool engagement region 19, with which the cap nut 12 can be gripped by a tool (not depicted). In addition the cap nut 12 has a cap 16 with a centring point 7, with which the cap nut 12, and the electrical contact stud 1, onto which the cap nut 12 is screwed, can be gripped. A recess 22 on a sealing 25 flange 8 of the cap nut 12 forms a sealing lip 15, with which a particularly efficient seal of the contact face 4 of the electrical contact stud 1 is effected.

Fig. 4 shows the cap nut 12 according to the invention according to Fig. 3 in cross-section with the thread orifice 13, the diameter DG of the thread orifice 13 and 30 the tool engagement region 19.

The electrical contact system according to the invention is shown in Fig. 5 in side view. The cap nut 12 according to the invention made of plastics material can be seen with the centring point 17, the cap 16, the tool engagement region 19 and the sealing flange 8, as well as the electrical contact stud 1 according to the invention with the shank 2, the external thread 5, the contact face 4, the contact flange 3, which has a tool engagement region 20 and the welding portion 23 with the conical projection 9. The cap nut 12 is screwed onto the contact stud 1 and the contact face 4 is protected by the sealing flange 8.

Fig. 6 shows the electrical contact system according to the invention according to Fig. 5 in cross-section with the tool engagement regions 19, 20 and the shank 2.

Protection of the contact face 4 from being covered with paint is shown in the detailed view of Fig. 7. The sealing flange 8, which has a sealing lip 15, produced by an obtuse-angled, conical recess 22, can be seen. The sealing lip 15 is pressed against the contact face 4, whereby a deformation 14 is caused. The deformation effects on the one hand a seal and on the other hand, owing to the elastic deformation of the cap nut 12, self-catching of the cap nut 12.

Fig. 8 shows the method according to the invention for fastening an electrical contact to a workpiece 11 to be painted. The possible sequences are illustrated in the rows.

In the top row the cap nut 12 is first partially screwed onto the electrical contact stud 1. Then the contact stud 1 is welded onto the workpiece 11, here designed as sheet metal. With the aid of the holding tongs 18 the electric current for welding is transferred onto the electrical contact stud 1. The cap nut 12 is subsequently firmly screwed onto the contact stud 1 for sealing. Then painting takes place. The cap nut 12 is subsequently loosened, so that an electrical contact shoe 21 can be inserted, which by pressing is finally electrically contacted with the contact face 4 with the aid of the cap nut 12.

In the second row the cap nut 12 is first firmly screwed onto the contact stud 1. The contact stud 1 is held by the holding tool 18 and fastened to the workpiece 11 by a welding process. Then painting takes place. The cap nut 12 is partially loosened and the contact shoe 21 is inserted. By tightening the cap nut 12 with a torque of for example approximately 8 Nm the contact shoe 21 is fastened and well contacted electrically with the contact face 4.

In the third line the contact stud 1 is held by the holding tool 18 and welded on. The cap nut 12 is subsequently screwed down. Then painting takes place. The contact 10 shoe 21 is inserted in the described manner.

The invention relates to an electrical contact stud 1, a cap nut 12 made of plastics material, an electrical contact system for fastening an electrical contact, as well as a method for fastening an electrical contact to a workpiece 11 to be painted. 15 The invention is characterised firstly in that the cap nut is made of plastics material and can therefore be produced economically. In addition the required maximum torques for generating the electrical and mechanical contact can be comparatively small, can be in particular 8 Nm, whereby fastening an electrical contact is made possible even with thin sheets of metal with sheet metal thicknesses of less than 0.5 20 mm without deformations.

**CLAIMS**

1. Electrical contact stud (1), in particular for fastening an electrical earth contact, with a shank (2), having an external thread (5); and an adjoining contact flange (3) with a contact face (4) facing the shank, characterised in that the shank (2) with the external thread is designed for screwing down a cap nut made of plastics material with a torque of at least 4 Nm, in particular at least 6 Nm, preferably approximately 8 Nm.
- 10 2. Electrical contact stud (1) according to claim 1, characterised in that the ratio of the inclination (SA) of the external thread (5) to the diameter (DS) of the shank (2) is at least 1:5, in particular at least 1:4, preferably approximately 1:3.
- 15 3. Electrical contact stud (1) according to claim 1 or 2, characterised in that the ratio of the thickness (DF) of the contact flange (3) to the diameter (DS) of the shank (2) is at least 1:2, in particular 1:1.5, preferably approximately 1:1.
- 20 4. Electrical contact stud (1) according to any one of the preceding claims, characterised in that the contact flange (3) has on its side opposite the contact face a welding portion (23), preferably with a blunt conical projection (9).
- 25 5. Electrical contact stud (1) according to any one of the preceding claims, characterised in that the contact flange (3) of the stud (1) has a sufficient axial extension to form a contact face for the introduction of the welding current.
6. Electrical contact stud (1) according to any one of the preceding claims, characterised in that the contact flange (3) has a tool engagement region (20).
- 30 7. Electrical contact stud (1) according to any one of the preceding claims, characterised in that the shank (2) has a bezel (10) on its open end.

8. Electrical contact stud (1) according to any one of the preceding claims, characterised in that the contact stud (1) has a particularly corrosion-proof and electrically contact-conveying coating, in particular a tin-zinc alloy.
- 5 9. Cap nut (12) made of plastics material, in particular for fastening an electrical earth contact, with a cap (16) and a front end (17), wherein the front end (17) has a thread orifice (13) containing an internal thread (6), characterised in that the internal thread (6) is designed in such a way and the material of the cap nut (12) is of such a kind that the cap nut (12) can be tightened on a corresponding external thread (5) against a contact face (4) with a torque of at least 4 Nm, in particular 6 Nm, preferably 8 Nm.
- 10 10. Cap nut (12) according to claim 9, characterised in that the ratio of the inclination of the internal thread (6) to the diameter (DG) of the thread orifice (13) is at least 1:5, in particular at least 1:4, preferably approximately 1:3.
- 15 11. Cap nut (12) according to claim 9 or 10, characterised in that the cap nut (12) is made of conductive plastics material.
- 20 12. Cap nut (12) according to claim 11, characterised in that the conductivity of the plastics material is created by an enclosed metal element.
13. Cap nut (12) according to claim 12, characterised in that enclosed metal elements are formed as metal filaments.
- 25 14. Cap nut (12) according to any one of claims 9 to 13 , characterised in that the cap nut (12) is made of a plastics material with particular resistance to mechanical strain, in particular polyamide reinforced by glass fibres.
- 30 15. Cap nut (12) according to claim 14, characterised in that the plastics material contains at least 10%, in particular at least 20%, preferably approximately 35% glass fibres.

16. Cap nut (12) according to any one of claims 9 to 15, characterised in that the cap (16) has a centring point (7).
- 5 17. Cap nut (12) according to any one of claims 9 to 16, characterised in that the front end (17) has a sealing flange (8).
18. Cap nut (12) according to claim 17, characterised in that the diameter of the sealing flange (8) does not exceed the diameter of the contact face (4).
- 10 19. Cap nut (12) according to any one of claims 9 to 18, characterised in that the front end (17) has a concave surface or an obtuse-angled, conical recess (22), so a sealing lip (15) is formed on the outside.
- 15 20. Cap nut (12) according to any one of claims 9 to 19, characterised in that the internal thread (6) is formed with a dimension smaller than that of the external thread (5).
21. Cap nut (12) according to any one of claims 9 to 20, characterised in that the cap (16) has a tool engagement region (19).
- 20 22. Electrical contact system, in particular for fastening an electrical earth contact, comprising an electrical contact stud (1), in particular according to any one of claims 1 to 7, and a cap nut (12) made of plastics material, in particular according to any one of claims 8 to 16, characterised in that the electrical contact stud (1) has a shank (2) with an external thread (5) and an adjoining contact flange (3), and the cap nut (12) has a front end (17) with thread orifice (13) containing an internal thread (6), wherein the cap nut (12) can be tightened with a torque of at least 4 Nm, in particular 6 Nm, preferably 8 Nm, against the contact flange (3).

23. Electrical contact system according to claim 22, characterised in that to produce self-catching the inclination of the internal thread (6) is different from the inclination of the external thread (5).
- 5 24. Electrical contact system according to any one of claims 22 or 23, characterised in that to produce self-catching the diameter (DS) of the shank (2) is at least 2%, in particular at least 6%, preferably approximately 8% larger than the diameter (DG) of the thread orifice (13).
- 10 25. Method of fastening an electrical contact to a workpiece (11) to be painted using an electrical contact stud (1), in particular an electrical contact stud (1) according to any one of claims 1 to 7, and a cap nut (12), in particular a cap nut (12) according to any one of claims 8 to 16, with the following method steps:
- tightening the cap nut (12) on the contact stud (1) with a torque of at least 1
  - 15 Nm, maximum 4Nm, preferably approximately 3 Nm;
  - fastening the contact stud (1) to the workpiece (11);
  - applying the paint to the workpiece (11);
  - loosening the cap nut (12) from the contact stud (1);
  - intermediate placing of an electrical contact shoe (21);
- 20 - pressing the electrical contact shoe (21) by tightening the cap nut (12) with a torque of more than 4 Nm, preferably more than 6 Nm, in particular approximately 8 Nm.
26. Method according to claim 25, characterised in that the cap nut (12) is made of
- 25 plastics material.
27. Method according to claim 26, characterised in that the cap nut (12) is deformed elastically or plastically on tightening.

**ABSTRACT****ELECTRICAL CAPPED CONTACT STUD AND METHOD OF  
FASTENING AN ELECTRICAL CONTACT**

5

The invention relates to an electrical contact stud (1), a cap nut (12) made of plastics material, an electrical contact system for fastening an electrical contact and a method for fastening an electrical contact to a workpiece (11) to be painted. The invention is characterised in that a cap nut (12), which can be economically produced, 10 made of plastics material, which does not necessarily have to be electrically conducting, is used for fastening an electrical contact shoe (21). As a plastics material nut can be designed as self-securing, the required maximum torques for producing the contact are relatively small, in particular, for example 8 Nm, whereby fastening an electrical contact is made possible even with thin sheets of metal with sheet metal 15 thicknesses of less than 0.6 mm without deformations. The cap nut (12) made of plastics material serves in a first step as a seal against the penetration of paint into the electrical contact region and in a second step for fastening a contact shoe (21).
